ABSTRACT

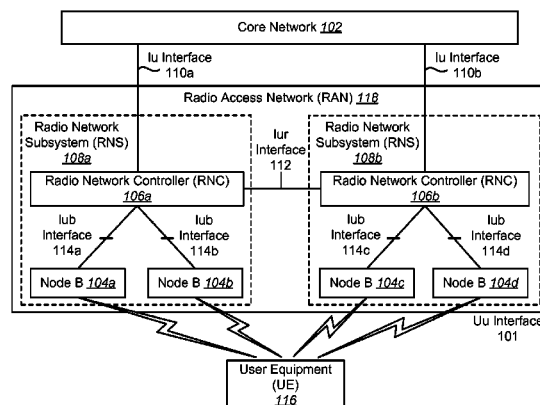

A method for reducing energy consumption of a base station is described. A first pilot channel is transmitted via a first antenna using a first downlink power amplifier. A second pilot channel is transmitted via a second antenna using a second downlink power amplifier. It is determined that no multiple-input and multiple-output users are in a cell corresponding to the base station. The second pilot channel is shut off.

REDUCING ENERGY CONSUMPTION IN A BASESTATION BY SHUTTING OFF SECONDARY PILOT TRANSMISSION IN ABSENCE OF MIMO USERS

CLAIM OF PRIORITY

The present application for patent is a Divisional and claims priority to patent application Ser. No. 12/985,732 entitled "APPARATUS AND METHOD FOR REDUCING ENERGY CONSUMPTION BY CELLULAR BASE STATIONS" filed Jan. 6, 2011, now allowed, which claims priority from U.S. Provisional Patent Application Ser. No. 61/294,047, filed Jan. 11, 2010, for "ENERGY SAVINGS IN CELLULAR BASE STATIONS," all of which are incorporated by reference herein.

TECHNICAL FIELD

The present disclosure relates generally to wireless communication systems. More specifically, the present disclosure relates to systems and methods for energy savings in cellular base stations.

BACKGROUND

Wireless communication systems are widely deployed to provide various types of communication content such as voice, video, data, and so on. These systems may be multiple-access systems capable of supporting simultaneous communication of multiple terminals with one or more base stations.

As precious natural resources are consumed, it has become beneficial to reduce the power consumption of computing devices. One such device where power consumption may be reduced is a base station.

Base stations are always on and always consuming power. Oftentimes portions of base stations are on when no wireless communication devices are near the base station or utilizing the services of the base station. Benefits may be realized by reducing the energy consumption of base stations.

SUMMARY

A method for reducing energy consumption of a base station is described. A first pilot channel is transmitted via a first antenna using a first downlink power amplifier. A second pilot channel is transmitted via a second antenna using a second downlink power amplifier. It is determined that no multiple-input and multiple-output users are in a cell corresponding to the base station. The second pilot channel is shut off.

Shutting off the second pilot channel may include shutting off the second downlink power amplifier. The base station may be a Node B. The method may be performed by a radio network controller via instructions sent to the base station. The first pilot channel and the second pilot channel may be used for multiple-input and multiple-output transmissions to a user equipment.

A method for reducing energy consumption of a base station is also described. The method includes communicating with one or more user equipments using n carriers. The method also includes determining that a load of one or more of the n carriers is below a carrier load threshold. One or more user equipments are redirected from the one or more carriers with loads below the carrier load threshold to one or more other carriers. The one or more carriers with loads below the carrier load threshold are turned off.

2

Turning off the one or more carriers with loads below the carrier load threshold may include turning off physical equipment corresponding to the one or more carriers with loads below the carrier load threshold. Physical equipment may include a downlink power amplifier. Physical equipment may also include at least one of channel cards, digital signal processors, field programmable gate arrays, application-specific integrated circuits, clocks and backhaul interface units on a baseband unit. The method may include communicating with the one or more user equipments using the one or more carriers with loads above the carrier load threshold.

Redirecting the one or more user equipments from the one or more carriers with loads below the carrier load threshold to the one or more carriers with loads above the carrier load threshold may include instructing the one or more user equipments to switch to a different modulation and coding scheme or to switch to a different frequency.

It may be determined whether a total load of the one or more carriers with loads above the carrier load threshold is above a combined carrier load threshold. If the total load of the one or more carriers with loads above the carrier load threshold is above the combined load threshold, a previously-switched-off carrier may be turned on and one or more user equipments may be redirected from the one or more carriers with loads above the carrier load threshold to the previously-turned-off carrier. Turning on the previously-switched-off carrier may include turning on physical equipment corresponding to the previously-switched-off carrier.

The method may be performed by the base station. The base station may be a Node B. The method may also be performed by a radio network controller (RNC) via instructions sent to the base station.

A method for reducing energy consumption of a base station is also described. The method includes communicating with one or more user equipments using one or more carriers. It is determined that a load of any of the one or more carriers is below a carrier load threshold. One or more baseband unit subunits to disable on the one or more carriers are determined. The one or more of the baseband unit subunits are disabled. The method further includes communicating with the one or more user equipments using the one or more carriers and only the baseband unit subunits that have not been disabled.

The method may further include determining that a load of any of the one or more carriers is above the carrier load threshold. One or more baseband unit subunits that have been disabled may be re-enabled. The baseband unit subunits may include channel cards, digital signal processors, field programmable gate arrays, application-specific integrated circuits, clocks and backhaul interface units. The base station may be a Node B. The method may be performed by a radio network controller (RNC) via instructions sent to the base station.

A wireless device configured for reducing energy consumption is described. The wireless device includes a processor, memory in electronic communication with the processor and instructions stored in the memory. The instructions are executable by the processor to transmit a first pilot channel via a first antenna using a first downlink power amplifier. The instructions are also executable by the processor to transmit a second pilot channel via a second antenna using a second downlink power amplifier. The instructions are further executable by the processor to determine that no multiple-input and multiple-output users are in a cell corresponding to the wireless device. The instructions are further executable by the processor to shut off the second pilot channel.

A wireless device configured for reducing energy consumption is also described. The wireless device includes a

processor, memory in electronic communication with the processor and instructions stored in the memory. The instructions are executable by the processor to communicate with one or more user equipments using n carriers. The instructions are also executable by the processor to determine that a load of one or more of the n carriers is below a carrier load threshold. The instructions are further executable by the processor to redirect one or more user equipments from the one or more carriers with loads below the carrier load threshold to one or more other carriers. The instructions are also executable by the processor to turn off the one or more carriers with loads below the carrier load threshold.

A wireless device configured for reducing energy consumption is further described. The wireless device includes a processor, memory in electronic communication with the processor and instructions stored in the memory. The instructions are executable by the processor to communicate with one or more user equipments using one or more carriers. The instructions are also executable by the processor to determine that a load of any of the one or more carriers is below a carrier load threshold. The instructions are further executable by the processor to determine one or more baseband unit subunits to disable on the one or more carriers. The instructions are also executable by the processor to disable the one or more baseband unit subunits. The instructions are further executable by the processor to communicate with the one or more user equipments using the one or more carriers and only the baseband unit subunits that have not been disabled.

A wireless device configured for reducing energy consumption is described. The wireless device includes means for transmitting a first pilot channel via a first antenna using a first downlink power amplifier. The wireless device also includes means for transmitting a second pilot channel via a second antenna using a second downlink power amplifier. The wireless device further includes means for determining that no multiple-input and multiple-output users are in a cell corresponding to the wireless device. The wireless device also includes means for shutting off the second pilot channel.

A computer-program product for reducing energy consumption of a base station is described. The computer-program product includes a non-transitory computer-readable medium having instructions thereon. The instructions include code for causing a base station to transmit a first pilot channel via a first antenna using a first downlink power amplifier. The instructions also include code for causing the base station to transmit a second pilot channel via a second antenna using a second downlink power amplifier. The instructions further include code for causing the base station to determine that no multiple-input and multiple-output users are in a cell corresponding to the base station. The instructions also include code for causing the base station to shut off the second pilot channel.

A wireless device configured for reducing energy consumption is also described. The wireless device includes means for communicating with one or more user equipments using n carriers. The wireless device also includes means for determining that a load of one or more of the n carriers is below a carrier load threshold. The wireless device further includes means for redirecting one or more user equipments from the one or more carriers with loads below the carrier load threshold to one or more other carriers. The wireless device also includes means for turning off the one or more carriers with loads below the carrier load threshold.

A wireless device configured for reducing energy consumption is further described. The wireless device includes means for communicating with one or more user equipments using one or more carriers. The wireless device also includes

means for determining that a load of any of the one or more carriers is below a carrier load threshold. The wireless device further includes means for determining one or more baseband unit subunits to disable on the one or more carriers. The wireless device also includes means for disabling the one or more baseband unit subunits. The wireless device further includes means for communicating with the one or more user equipments using the one or more carriers and only the baseband unit subunits that have not been disabled.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 shows a wireless communication system with multiple wireless devices;

FIG. 2 is a block diagram illustrating selected components of a wireless communication system;

FIG. 3 is a block diagram illustrating a Node B and a radio network controller (RNC) interface with a packet network interface;

FIG. 4 is a block diagram of a Node B for use in the present systems and methods;

FIG. 5 is a block diagram of a Node B with multiple radio equipments (RE) that are separated from the radio equipment control (REC);

FIG. 6 is a flow diagram of a method for reducing power consumption of a Node B by switching off multiple-input and multiple-output (MIMO) transmissions;

FIG. 7 is a flow diagram of a method for reducing power consumption of a Node B by shutting off one or more carriers;

FIG. 8 is a flow diagram of a method for disabling baseband unit (BBU) subunits to reduce energy consumption on a Node B;

FIG. 9 is a block diagram of a transmitter structure and/or process implemented in a Node B;

FIG. 10 illustrates certain components that may be included within a Node B; and

FIG. 11 illustrates certain components that may be included within a radio network controller (RNC).

DETAILED DESCRIPTION

The 3rd Generation Partnership Project (3GPP) is a collaboration between groups of telecommunications associations that aims to define a globally applicable 3rd generation (3G) mobile phone specification. The 3GPP may define specifications for the next generation of mobile networks, mobile systems and mobile devices. In 3GPP, a mobile station or device may be referred to as a “user equipment” (UE).

FIG. 1 shows a wireless communication system 100 with multiple wireless devices. Wireless communication systems 100 are widely deployed to provide various types of communication content such as voice, data, and so on. A wireless device may be a Node B 104a-d or a user equipment (UE) 116.

The wireless communication system 100 may include a radio access network (RAN) 118 operating according to Universal Mobile Telecommunications System (UMTS). A radio access network (RAN) 118 may include one or more radio network subsystems (RNS) 108a-b. Each radio network subsystem (RNS) 108 may include one or more Node Bs 104 and one or more radio network controllers (RNCs) 106a-b. A radio access network (RAN) 118 may also be referred to as a “radio network” or an “access network.” The radio access network (RAN) 118 may be a UMTS Terrestrial Radio Access Network (UTRAN). A UMTS Terrestrial Radio Access Network (UTRAN) is a collective term for the Node Bs 104 and the control equipment for the Node Bs 104 (or

radio network controllers (RNCs) **106a-b**) it contains which make up the UMTS radio access network (RAN) **118**. This is a third generation (3G) communications network which can carry both real-time circuit-switched and internet protocol (IP) based packet switched traffic types. The UTRAN provides an air interface access method for the user equipment (UE) **116**. Connectivity is provided between the user equipment (UE) **116** and a core network **102** by the UTRAN. The radio access network (RAN) **118** may transport data packets between multiple user equipments (UEs) **116**.

The UTRAN may be connected internally or externally using four interfaces: the Iu interface **110a-b**, the Uu interface **101**, the Iub interface **114a-d** and the Iur interface **112**. The UTRAN may be attached to a Global System for Mobile Communications (GSM) core network **102** via an external interface referred to as the Iu interface **110**. One or more radio network controllers (RNCs) **106** may support the Iu interface **110**. In addition, a radio network controller (RNC) **106** may manage a set of base stations called Node Bs **104** through the Iub interfaces **114**. The Iur interface **112** may connect two radio network controllers (RNCs) **106** with each other. The UTRAN is largely autonomous from the core network **102** since the radio network controllers (RNCs) **106** are interconnected by the Iur interface **112**. The Uu interface **101** also connects the Node B **104** with a user equipment (UE) **116**, while the Iub interface **114** is an internal interface that connects the radio network controller (RNC) **106** with the Node B **104**.

The radio access network (RAN) **118** may be further connected to additional networks outside the radio access network (RAN) **118**, such as a corporate intranet, the Internet or a conventional public switched telephone network (PSTN) and may transport data packets between each user equipment (UE) **116** and the outside networks.

FIG. 2 is a block diagram illustrating selected components of a wireless communication system **200**. The wireless communication system **200** may include radio network controllers (RNCs) **206a-d** coupled to Node Bs **204a-c** (also referred to as base stations or wireless base transceiver stations) via Iub interfaces **214a-c**. The Node Bs **204** may communicate with user equipments (UEs) **216a-e** through corresponding wireless connections. A user equipment (UE) **216** may also be referred to as a remote station, a mobile station or a subscriber station.

A communications channel may include a downlink for transmissions from a Node B **204** to a user equipment (UE) **216**, and an uplink for transmissions from a user equipment (UE) **216** to a Node B **204**. A radio network controller (RNC) **206** may provide control functionalities for one or more Node Bs **204**. Each radio network controller (RNC) **206** may be coupled to a public switched telephone network (PSTN) **220** through a mobile switching center (MSC) **222a-b**.

In one configuration, a radio network controller (RNC) **206** may be coupled to a packet switched network (PSN) (not shown) through a packet data server node (PDSN) (not shown). Data interchange between various network elements, such as a radio network controller (RNC) **206** and a packet data server node, can be implemented using any number of protocols, for example, the Internet Protocol (IP), an asynchronous transfer mode (ATM) protocol, T1, E1, frame relay and other protocols.

A radio network controller (RNC) **206** may fill multiple roles. For example, the radio network controller (RNC) **206** may control the admission of new mobiles or services attempting to use a Node B **204**. The radio network controller (RNC) **206** may also control a Node B **204**. Controlling admission ensures that user equipments (UEs) **216** are allo-

cated radio resources (bandwidth and signal/noise ratio) up to what the network has available. It is where the Iub interface **214** terminates. A radio network controller (RNC) **206** may act as a serving radio network controller (RNC) **206** that terminates the user equipment's (UE's) **216** link layer communications. The serving radio network controller (RNC) **206** may also control the admission of new user equipments (UEs) or services attempting to use the core network **102** over the Iu interface **110**.

In a multiple-input and multiple-output (MIMO) system, there are N (# of transmitter antennas) by M (# of receiver antennas) signal paths from the transmit and the receive antennas, and the signals on these paths are not identical. A multiple-input and multiple-output (MIMO) system creates multiple data transmission pipes. The pipes are orthogonal in the space-time domain. The number of pipes equals the rank of the system. Since these pipes are orthogonal in the space-time domain, they create little interference with each other. The data pipes are realized with proper digital signal processing by properly combining signals on the N×M paths. A transmission pipe may not correspond to an antenna transmission chain or any one particular transmission path.

Communication systems may use a single carrier frequency or multiple carrier frequencies. Each communication link between a user equipment (UE) **216** and a Node B **204a** may incorporate a different number of carrier frequencies. A user equipment (UE) **216** may be any data device that communicates through a wireless channel. A user equipment (UE) **216** may be any of a number of types of devices including but not limited to a PC card, a compact flash, an external or internal modem, or a wireless phone. A user equipment (UE) **216** may be mobile or stationary.

A user equipment (UE) **216** that has established an active traffic channel connection with one or more Node Bs **204** is referred to as an active user equipment (UE) **216**, and is said to be in a traffic state. A user equipment (UE) **216** that is in the process of establishing an active traffic channel connection with one or more Node Bs **204** is said to be in a connection setup state.

FIG. 3 is a block diagram illustrating a Node B **304** and a radio network controller (RNC) **306** interfaced with a packet network interface **324**. Only one Node B **304** is shown for simplicity. The Node B **304** and the radio network controller (RNC) **306** may be part of a radio network subsystem (RNS) **308**. The quantity of data to be transmitted by the Node B **304** to a user equipment (UE) **116** may be retrieved from a data queue **334** in the Node B **304** and provided to the channel element **332** for transmission to the user equipment (UE) **116** associated with the data queue **334** via a radio frequency (RF) unit **336**.

The radio network controller (RNC) **306** interfaces with a Public Switched Telephone Network (PSTN) **320** through a mobile switching center (MSC) **322**. Also, the radio network controller (RNC) **306** interfaces with a Node B **304**. In addition, the radio network controller (RNC) **306** may interface with a Packet Network Interface **324**. The radio network controller (RNC) **306** may coordinate the communication between a user equipment (UE) **116** in the communication system and other users connected to the packet network interface **324** and the public switched telephone network (PSTN) **320**. The public switched telephone network (PSTN) **320** may interface with users through a standard telephone network (not shown).

The radio network controller (RNC) **306** may include many selector elements **338**. Each selector element **338** may be assigned to control communication between one or more Node Bs **304** and one user equipment (UE) **116**. If a selector

element **338** has not been assigned to a given user equipment (UE) **116**, a call control processor **340** may be informed of the need to page the user equipment (UE) **116**. The call control processor **340** may then direct the Node B **304** to page the user equipment (UE) **116**.

The data source **326** may include a quantity of data that is to be transmitted to a given user equipment (UE) **116**. The data source **326** may provide the data to a packet network interface **324**. The packet network interface **324** receives the data and routes the data to the selector element **338**. The selector element **338** then transmits the data to a Node B **304** that is in communication with the target user equipment (UE) **116**. Each Node B **304** may maintain a data queue **334** that stores the data to be transmitted to the user equipment (UE) **116**.

For each data packet, the channel element **332** may insert the necessary control fields. In one configuration, the channel element **332** may perform a cyclic redundancy check (CRC) to encode the data packet and control fields and insert a set of code tail bits. The data packet, control fields, CRC parity bits and code tail bits form a formatted packet. In one configuration, the channel element **332** may then encode the formatted packet and interleave (or reorder) the symbols within the encoded packet. The interleaved packet may be covered with a Walsh code and spread with the short PNI and PNQ codes. The spread data is provided to a radio frequency (RF) unit **336** that quadrature modulates, filters and amplifies the signal. The downlink signal is transmitted over the air through an antenna to the user equipment (UE) **116**.

The Node B **304** may include a control unit **330** and memory **328**. The control unit **330** may control each of the components of the Node B **304** according to software stored in the memory **328**.

FIG. 4 is a block diagram of a Node B **404** for use in the present systems and methods. The Node B **404** of FIG. 4 may be one configuration of the Node Bs **104** illustrated in FIG. 1. In systems where multiple carriers have been deployed, energy management techniques may be introduced at the Node B **404** based on the measured traffic in the system.

Potential solutions enabling energy savings within a UMTS Node B **404** may exist. These solutions may consider the impacts on the time for legacy and new user equipments (UEs) **116** to gain access to service from a Node B **404** and the impacts on legacy and new user equipments (UEs) **116** (e.g., power consumption and mobility). Solutions that are backwards-compatible and non-backwards-compatible may both be considered.

A Node B **404** may include two basic building blocks: a baseband unit (BBU) **442** and a radio equipment (RE) **456**. The baseband unit (BBU) **442** may also be referred to as a radio equipment control (REC). Both the baseband unit (BBU) **442** and the radio equipment (RE) **456** may be co-located in a conventional radio base station design. The baseband unit (BBU) **442** may include the radio functions of the digital baseband domain. The radio equipment (RE) **456** may include the analog radio frequency functions.

A baseband unit (BBU) **442** may include subunits such as channel cards **444**, digital signal processors (DSPs) **446**, field programmable gate arrays (FPGAs) **448**, application specific integrated circuits (ASICs) **450**, clocks **452** and backhaul interface units **454**. Portions of these subunits may be turned

off to save power when they are not needed. For example, a baseband unit (BBU) **442** may include three channel cards **444**. Depending on the load, two of the channel cards **444** may be shut off to save power. Similarly, a subset of the EIs or TIs in the backhaul interface units **454** may be shut off.

The radio equipment (RE) **456** may include a first downlink power amplifier **458a** coupled to a first antenna **460a**. If the Node B **404** is used for multiple-input and multiple-output (MIMO) transmissions, the radio equipment (RE) **456** may also include a second downlink power amplifier **458b** coupled to a second antenna **460b**. In one configuration, a radio equipment (RE) **456** may include more than two downlink power amplifiers **458**. For example, a Node B **404** may be using multiple carriers (non-MIMO) across multiple power amplifiers **458**. The Node B **404** may shut off one or more downlink power amplifiers **458** to reduce the power consumption of the Node B **404**. If the Node B **404** shuts off a carrier, the Node B **404** may shut off the downlink power amplifiers **458** associated with the carrier.

Reduction in energy consumption may be accomplished by determining the energy consumption breakdown in existing Node Bs **404**, establishing Node B **404** energy saving targets and identifying solutions based on the existing Uu interface **101** that rely on Node B **404** implementation enhancements as well as UTRAN operation. If the targets are still not met, solutions may be identified that can help achieve the targets by way of modifications to 3GPP specifications. Each solution may need to be characterized based on the impact to the system.

The Node B **404** may include an energy management module **462**. The Node B **404** may use the energy management module **462** to determine when to make adjustments that may reduce the energy consumption of the Node B **404**. The energy management module **462** may include a carrier load threshold **464**. The carrier load threshold **464** may be a preset threshold that defines the minimum carrier load when the Node B **404** shuts off one or more carriers or one or more subunits of the baseband unit (BBU) **442** to reduce the power consumption of the Node B **404**. The energy management module **462** may also include a combined carrier load threshold **466**. If the Node B **404** has shut off one or more carriers to conserve energy, the combined carrier load threshold **466** may be a preset maximum load on the carriers that are turned on before the Node B **404** turns a shut off carrier back on. The carrier load threshold **464** is discussed in additional detail below in relation to FIG. 6 and FIG. 7. The combined carrier load threshold **466** is discussed in additional detail below in relation to FIG. 6 and FIG. 7.

FIG. 5 is a block diagram of a Node B **504** with multiple radio equipments (RE) **556a-b** that are separated from the radio equipment control (REC) **542**. The radio equipment control (REC) **542** may be a Baseband Unit (BBU) **442**. Each radio equipment (RE) **556** may be close to an antenna while the radio equipment control (REC) **542** is located in a conveniently accessible site. For the UMTS radio access network (RAN) **118**, the radio equipment control (REC) **542** provides access to a radio network controller (RNC) **106** via the Iub interface **114**, whereas the radio equipment (RE) **556** serves as the air interface, called the Uu interface **101**, to the user equipment (UE) **116**. Table 1 lists the functions performed both on the uplink and the downlink by the radio equipment control (REC) **542** and the radio equipment (RE) **556**.

TABLE 1

Functions of REC or BBU		Functions of RE	
Downlink	Uplink	Downlink	Uplink
Radio base station control & management			
Iub transport			
Iub Frame protocols		RRC Channel Filtering	
Channel Coding	Channel De-coding	D/A conversion	A/D conversion
		Up Conversion	Down Conversion
Interleaving	De-Interleaving	ON/OFF control of each carrier	Automatic Gain Control
Spreading	De-spreading	Carrier Multiplexing	Carrier De-multiplexing
Scrambling	De-scrambling	Power amplification and limiting	Low Noise Amplification
MIMO processing		Antenna supervision	
Adding of physical channels	Signal distribution to signal processing units		
Transmit Power Control of each physical channel	Transmit Power Control & Feedback	RF filtering	RF filtering
Frame and slot signal generation (including clock stabilization)	Information detection		
Reference Frequency Generation			
Measurements		Measurements	

FIG. 6 is a flow diagram of a method 600 for reducing power consumption of a Node B 404 by switching off multiple-input and multiple-output (MIMO) transmissions. The method 600 may be performed by a Node B 404. In one configuration, the method 600 may be performed by a radio network controller (RNC) 106 via instructions sent to a Node B 404. The Node B 404 may transmit 602 a first pilot channel via a first antenna 460a using a first downlink power amplifier 458a and a second pilot channel via a second antenna 460b using a second downlink power amplifier 458b. The pilot channels may be used for multiple-input and multiple-output (MIMO) transmissions to one or more user equipments (UEs) 116 that are in communication with the Node B 404.

The Node B 404 may determine 604 whether there are any multiple-input and multiple-output (MIMO) users in the cell. A multiple-input and multiple-output (MIMO) user may refer to a user equipment (UE) 116 that is within the boundaries covered by a Node B 404 that is capable/configured for multiple-input and multiple-output (MIMO) communications. If there are multiple-input and multiple-output (MIMO) users in the cell, the Node B 404 may continue transmitting 602 both the first pilot channel via the first antenna 460a using the first downlink power amplifier 458a and the second pilot channel via the second antenna 460b using the second downlink power amplifier 458b.

If there are no multiple-input and multiple-output (MIMO) users in the cell, the Node B 404 may shut off 606 the second pilot channel and the second downlink power amplifier 458b. This may lead to significant energy savings. The Node B 404 may thus reduce the power consumption of the Node B 404 by eliminating the power used by the second power amplifier 458b to transmit the second pilot channel during times when the second pilot channel is not needed. The Node B 404 may transmit 608 only the first pilot channel via the first antenna 460a using the first downlink power amplifier 458a. The Node B 404 may then again determine 604 whether there are any multiple-input and multiple-output (MIMO) users in the cell.

FIG. 7 is a flow diagram of a method 700 for reducing power consumption of a Node B 404 by shutting off one or more carriers. The method 700 may be performed by a Node B 404. In one configuration, the method 700 may be per-

formed by a radio network controller (RNC) 106 via instructions sent to a Node B 404. The Node B 404 may communicate 704 with one or more user equipments (UEs) 116 using n carriers.

The Node B 404 may determine 706 whether the load of any of the n carriers is below a carrier load threshold 464. The carrier load threshold 464 may be a preset threshold that defines the minimum number of user equipments (UEs) 116 utilizing a carrier before the Node B 404 redirects the user equipments (UEs) 116 to another carrier and shuts off the carrier. A user equipment (UE) 116 may be either a single-carrier user equipment (UE) 116 or a user equipment (UE) 116 that is capable of communicating with a Node B 404 using multiple carriers.

If the load of none of the n carriers is below the carrier load threshold 464, the Node B 404 may continue communicating 704 with the one or more user equipments (UEs) 116 using the n carriers. If the load of any of the carriers is below the carrier load threshold 464, the Node B 404 may redirect 708 one or more user equipments (UEs) 116 from the one or more carriers with loads below the carrier load threshold 464 to the one or more carriers with loads above the carrier load threshold 464 (this may apply until only one carrier remains). In one configuration, the Node B 404 may redirect 708 the one or more user equipments (UEs) 116 from the one or more carriers with loads below the carrier load threshold 464 to one or more carriers with loads that are currently below the carrier load threshold 464 (but that will have loads above the carrier load threshold 464 once the user equipments (UEs) 116 are redirected to them). Redirecting 708 the one or more user equipments (UEs) 116 from a carrier with a load below the carrier load threshold 464 to one or more carriers with loads above the carrier load threshold 464 may include instructing the one or more user equipments (UEs) 116 to switch to a different modulation and coding scheme and a different frequency. In one configuration, the Node B 404 may redirect the one or more user equipments (UEs) 116 to multiple carriers (i.e., not all the user equipments (UEs) 116 will go to the same carrier). In another configuration, the Node B 404 may reduce the amount of carriers that a user equipment (UE) 116 is configured for (i.e., if there is a small number of user equipments (UEs) 116 that can communicate using three different

carriers and not enough data demand (from the mix of user equipment (UE) 116 types and quantity), the Node B 404 may reconfigure those multi-carrier user equipments (UEs) 116 to use only one or two carriers and shut off the extra carrier(s).

The Node B 404 may then turn off 710 the one or more carriers with loads below the carrier load threshold and the physical equipment corresponding to the one or more carriers. By turning off one or more carriers during periods where the load is minimal, all or parts of the baseband unit (BBU) 442 and radio equipment (RE) 456 may be turned off, leading to a potentially large reduction in energy consumption at the Node B 404. The Node B 404 may communicate 712 with the one or more user equipments (UEs) 116 using the one or more carriers with loads above the carrier load threshold 464.

The Node B 404 may determine 713 whether the load of any of the one or more carriers is below the carrier load threshold 464. If the load of any of the one or more carriers is below the carrier load threshold 464, the Node B 404 may redirect 708 the one or more user equipments (UEs) 116 from the one or more carriers with loads below the carrier load threshold 464 to the one or more carriers with loads above the carrier load threshold 464. If the load of none of the n carriers is below the carrier load threshold 464, the Node B 404 may determine 714 whether the total load of the one or more carriers with loads above the carrier load threshold 464 is above a combined carrier threshold 466. The combined carrier threshold 466 may be a threshold used by the Node B 404 to determine when to resume communications using a previously-switched-off carrier after the previously-switched-off carrier has been turned off to reduce energy consumption.

If the total load of the one or more carriers is not above the combined carrier threshold 466, the Node B 404 may continue communicating 712 with the one or more user equipments (UEs) 116 using the one or more carriers with loads above the carrier load threshold 464. If the total load of the one or more carriers is above the combined carrier threshold 466, the Node B 404 may turn on 716 a previously-switched-off carrier and the physical equipment corresponding to the previously-switched-off carrier. The Node B 404 may next redirect 718 one or more user equipments (UEs) 116 from the one or more carriers with loads above the carrier load threshold 464 to the previously-switched-off carrier. The Node B 404 may then communicate 712 with the one or more user equipments (UEs) 116 using the one or more carriers with loads above the carrier load threshold 464.

FIG. 8 is a flow diagram of a method 800 for disabling baseband unit (BBU) 442 subunits to reduce energy consumption on a Node B 404. The method 800 may be performed by a Node B 404. In one configuration, the method 800 may be performed by a radio network controller (RNC) 106 via commands to the Node B 404. The Node B 404 may communicate 802 with one or more user equipments (UEs) 116 using one or more carriers and all baseband unit (BBU) 442 subunits for each of the one or more carriers. The Node B 404 may determine 804 whether the load of any of the one or more carriers is below a carrier load threshold 464. If the load of any of the one or more carriers is not below a carrier load threshold 464, the Node B 404 may continue communicating 802 with the one or more user equipments (UEs) 116 using the one or more carriers and all the baseband unit (BBU) 442 subunits for each of the one or more carriers.

If the load of any of the one or more carriers is below a carrier load threshold 464, the Node B 404 may determine 806 one or more baseband unit (BBU) 442 subunits to disable on the one or more carriers. For example, the Node B 404 may determine to disable channel cards 444, digital signal processors (DSPs) 446, field programmable gate arrays (FPGAs)

448, application-specific integrated circuits (ASICs) 450 or clocks 452 as a function of the load. The Node B 404 may also determine to disable backhaul interface units 454. In one configuration, the Node B 404 may determine 806 to disable the same baseband unit (BBU) 442 subunit for each of the one or more carriers. In another configuration, the Node B 404 may determine 806 different baseband unit (BBU) 442 subunits to disable for each carrier of the one or more carriers. The Node B 404 may then disable 808 the determined one or more baseband unit (BBU) 442 subunits. The Node B 404 may next communicate 810 with the one or more user equipments (UEs) 116 using the one or more carriers and only the baseband unit (BBU) 442 subunits that have not been disabled. In one configuration, the Node B 404 may use multiple carrier load thresholds 464 to iteratively shut off baseband unit (BBU) 442 subunits.

The Node B 404 may determine 812 whether the load of any of the one or more carriers with all baseband unit (BBU) 442 subunits enabled is below the carrier load threshold 464. If the load of any of the one or more carriers with all baseband unit (BBU) 442 subunits enabled is below the carrier load threshold 464, the Node B 404 may determine 806 one or more baseband unit (BBU) 442 subunits to disable on the one or more carriers. If none of the one or more carriers with all baseband unit (BBU) 442 subunits enabled has a load below the carrier load threshold 464, the Node B 404 may determine 813 whether the total load of the one or more carriers is above a combined carrier load threshold 466. If the total load of the one or more carriers is not above the combined carrier load threshold 466, the Node B 404 may continue communicating 810 with the one or more user equipments (UEs) 116 using the one or more carriers and only the baseband unit (BBU) 442 subunits that have not been disabled. If the total load of the one or more carriers is above the combined carrier load threshold 466, the Node B 404 may re-enable 814 some or all of the disabled baseband unit (BBU) 442 subunits. The Node B 404 may then return to communicating 810 with the one or more user equipments (UEs) 116 using the one or more carriers and only the baseband unit (BBU) 442 subunits that have not been disabled.

FIG. 9 is a block diagram of a transmitter structure and/or process implemented in a Node B 404. The functions and components shown in FIG. 9 may be implemented by software, hardware or a combination of software and hardware. Other functions may be added to FIG. 9 in addition to or instead of the functions shown in FIG. 9.

A data source 968 may provide data $d(t)$ 970 to a frame quality indicator (FQI)/encoder 972. The frame quality indicator (FQI)/encoder 972 may append a frame quality indicator (FQI) such as cyclic redundancy check (CRC) to the data $d(t)$ 970. The frame quality indicator (FQI)/encoder 972 may further encode the data $d(t)$ 970 using one or more coding schemes to provide encoded symbols 974. Each coding scheme may include one or more types of coding, e.g., convolutional coding, Turbo coding, block coding, repetition coding, other types of coding or no coding at all. Other coding schemes may include automatic repeat request (ARQ), hybrid ARQ (H-ARQ) and incremental redundancy repeat techniques. Different types of data may be encoded with different coding schemes.

An interleaver 976 may interleave the encoded data symbols 974 in time to combat fading. The interleaver 976 may output interleaved symbols 978. The interleaved symbols 978 may be mapped by a frame formatter 980 to a pre-defined frame format to produce a frame 982. In one configuration, a frame format may specify the frame as being composed of a plurality of sub-segments. In another configuration, sub-seg-

13

ments may be any successive portions of a frame **982** along a given dimension, e.g., time, frequency, code or any other dimension. A frame **982** may be composed of a fixed plurality of such sub-segments, each sub-segment containing a portion of the total number of symbols allocated to the frame. For example, in a wireless communication system that is configured according to the W-CDMA standard, a sub-segment may be defined as a slot. The interleaved symbols **978** may be segmented into a plurality **S** of sub-segments making up a frame **982**.

A frame formatter **980** may further specify the inclusion of control symbols (not shown) along with the interleaved symbols **978**. Such control symbols may include power control symbols, frame format information symbols, etc.

A modulator **984** may modulate the frame **982** to generate modulated data **986**. Examples of modulation techniques include binary phase shift keying (BPSK) and quadrature phase shift keying (QPSK). The modulator **984** may also repeat a sequence of modulated data **986**.

A baseband-to-radio-frequency (RF) conversion block **988** may convert the modulated data **986** to a radio frequency (RF) signal **990** for transmission via an antenna **960** over a wireless communication link to one or more user equipments (UEs) **116**.

FIG. **10** illustrates certain components that may be included within a Node B **1004**. A Node B **1004** may also be referred to as, and may include some or all of the functionality of, an access point, a broadcast transmitter, a base station, an evolved NodeB, etc. The Node B **1004** includes a processor **1003**. The processor **1003** may be a general purpose single- or multi-chip microprocessor (e.g., an ARM), a special purpose microprocessor (e.g., a digital signal processor (DSP)), a microcontroller, a programmable gate array, etc. The processor **1003** may be referred to as a central processing unit (CPU). Although just a single processor **1003** is shown in the Node B **1004** of FIG. **10**, in an alternative configuration, a combination of processors (e.g., an ARM and DSP) could be used.

The Node B **1004** also includes memory **1005**. The memory **1005** may be any electronic component capable of storing electronic information. The memory **1005** may be embodied as random access memory (RAM), read only memory (ROM), magnetic disk storage media, optical storage media, flash memory devices in RAM, on-board memory included with the processor, EPROM memory, EEPROM memory, registers, and so forth, including combinations thereof.

Data **1007a** and instructions **1009a** may be stored in the memory **1005**. The instructions **1009a** may be executable by the processor **1003** to implement the methods disclosed herein. Executing the instructions **1009a** may involve the use of the data **1007a** that is stored in the memory **1005**. When the processor **1003** executes the instructions **1009a**, various portions of the instructions **1009b** may be loaded onto the processor **1003**, and various pieces of data **1007b** may be loaded onto the processor **1003**.

The Node B **1004** may also include a transmitter **1011** and a receiver **1013** to allow transmission and reception of signals to and from the Node B **1004**. The transmitter **1011** and receiver **1013** may be collectively referred to as a transceiver **1015**. Multiple antennas **1017a-b** may be electrically coupled to the transceiver **1015**. The Node B **1004** may also include (not shown) multiple transmitters, multiple receivers, multiple transceivers and/or additional antennas.

The Node B **1004** may include a digital signal processor (DSP) **1021**. The Node B **1004** may also include a commu-

14

nications interface **1023**. The communications interface **1023** may allow a user to interact with the Node B **1004**.

The various components of the Node B **1004** may be coupled together by one or more buses, which may include a power bus, a control signal bus, a status signal bus, a data bus, etc. For simplicity, the various buses are illustrated in FIG. **10** as a bus system **1019**.

FIG. **11** illustrates certain components that may be included within a radio network controller (RNC) **1175**. A radio network controller (RNC) **1175** is a governing element in the UMTS radio access network (UTRAN) that is responsible for controlling the Node Bs **1004** that are connected to it. The radio network controller (RNC) **1175** may be connected to a circuit switched core network through a media gateway. The radio network controller (RNC) **1175** includes a processor **1103**. The processor **1103** may be a general purpose single- or multi-chip microprocessor (e.g., an ARM), a special purpose microprocessor (e.g., a digital signal processor (DSP)), a microcontroller, a programmable gate array, etc. The processor **1103** may be referred to as a central processing unit (CPU). Although just a single processor **1103** is shown in the radio network controller (RNC) **1175** of FIG. **11**, in an alternative configuration, a combination of processors (e.g., an ARM and DSP) could be used.

The radio network controller (RNC) **1175** also includes memory **1105**. The memory **1105** may be any electronic component capable of storing electronic information. The memory **1105** may be embodied as random access memory (RAM), read only memory (ROM), magnetic disk storage media, optical storage media, flash memory devices in RAM, on-board memory included with the processor, EPROM memory, EEPROM memory, registers, and so forth, including combinations thereof.

Data **1107a** and instructions **1109a** may be stored in the memory **1105**. The instructions **1109a** may be executable by the processor **1103** to implement the methods disclosed herein. Executing the instructions **1109a** may involve the use of the data **1107a** that is stored in the memory **1105**. When the processor **1103** executes the instructions **1109a**, various portions of the instructions **1109b** may be loaded onto the processor **1103**, and various pieces of data **1107b** may be loaded onto the processor **1103**.

The radio network controller (RNC) **1175** may include a digital signal processor (DSP) **1121**. The various components of the radio network controller (RNC) **1175** may be coupled together by one or more buses, which may include a power bus, a control signal bus, a status signal bus, a data bus, etc. For the sake of simplicity, the various buses are illustrated in FIG. **11** as a bus system **1119**.

The techniques described herein may be used for various communication systems, including communication systems that are based on an orthogonal multiplexing scheme. Examples of such communication systems include Orthogonal Frequency Division Multiple Access (OFDMA) systems, Single-Carrier Frequency Division Multiple Access (SC-FDMA) systems, and so forth. An OFDMA system utilizes orthogonal frequency division multiplexing (OFDM), which is a modulation technique that partitions the overall system bandwidth into multiple orthogonal sub-carriers. These sub-carriers may also be called tones, bins, etc. With OFDM, each sub-carrier may be independently modulated with data. An SC-FDMA system may utilize interleaved FDMA (IFDMA) to transmit on sub-carriers that are distributed across the system bandwidth, localized FDMA (LFDMA) to transmit on a block of adjacent sub-carriers, or enhanced FDMA (EFDMA) to transmit on multiple blocks of adjacent sub-

15

carriers. In general, modulation symbols are sent in the frequency domain with OFDM and in the time domain with SC-FDMA.

The term “determining” encompasses a wide variety of actions and, therefore, “determining” can include calculating, computing, processing, deriving, investigating, looking up (e.g., looking up in a table, a database or another data structure), ascertaining and the like. Also, “determining” can include receiving (e.g., receiving information), accessing (e.g., accessing data in a memory) and the like. Also, “determining” can include resolving, selecting, choosing, establishing and the like.

The phrase “based on” does not mean “based only on,” unless expressly specified otherwise. In other words, the phrase “based on” describes both “based only on” and “based at least on.”

The term “processor” should be interpreted broadly to encompass a general purpose processor, a central processing unit (CPU), a microprocessor, a digital signal processor (DSP), a controller, a microcontroller, a state machine, and so forth. Under some circumstances, a “processor” may refer to an application specific integrated circuit (ASIC), a programmable logic device (PLD), a field programmable gate array (FPGA), etc. The term “processor” may refer to a combination of processing devices, e.g., a combination of a DSP and a microprocessor, a plurality of microprocessors, one or more microprocessors in conjunction with a DSP core, or any other such configuration.

The term “memory” should be interpreted broadly to encompass any electronic component capable of storing electronic information. The term memory may refer to various types of processor-readable media such as random access memory (RAM), read-only memory (ROM), non-volatile random access memory (NVRAM), programmable read-only memory (PROM), erasable programmable read-only memory (EPROM), electrically erasable PROM (EEPROM), flash memory, magnetic or optical data storage, registers, etc. Memory is said to be in electronic communication with a processor if the processor can read information from and/or write information to the memory. Memory that is integral to a processor is in electronic communication with the processor.

The terms “instructions” and “code” should be interpreted broadly to include any type of computer-readable statement(s). For example, the terms “instructions” and “code” may refer to one or more programs, routines, sub-routines, functions, procedures, etc. “Instructions” and “code” may comprise a single computer-readable statement or many computer-readable statements.

The functions described herein may be implemented in software or firmware being executed by hardware. The functions may be stored as one or more instructions on a computer-readable medium. The terms “computer-readable medium” or “computer-program product” refers to any tangible storage medium that can be accessed by a computer or a processor. By way of example, and not limitation, a computer-readable medium may comprise RAM, ROM, EEPROM, CD-ROM or other optical disk storage, magnetic disk storage or other magnetic storage devices, or any other medium that can be used to carry or store desired program code in the form of instructions or data structures and that can be accessed by a computer. Disk and disc, as used herein, includes compact disc (CD), laser disc, optical disc, digital versatile disc (DVD), floppy disk and Blu-ray® disc where disks usually reproduce data magnetically, while discs reproduce data optically with lasers.

The methods disclosed herein comprise one or more steps or actions for achieving the described method. The method

16

steps and/or actions may be interchanged with one another without departing from the scope of the claims. In other words, unless a specific order of steps or actions is required for proper operation of the method that is being described, the order and/or use of specific steps and/or actions may be modified without departing from the scope of the claims.

Further, it should be appreciated that modules and/or other appropriate means for performing the methods and techniques described herein, such as those illustrated by FIGS. 6, 7 and 8, can be downloaded and/or otherwise obtained by a device. For example, a device may be coupled to a server to facilitate the transfer of means for performing the methods described herein. Alternatively, various methods described herein can be provided via a storage means (e.g., random access memory (RAM), read-only memory (ROM), a physical storage medium such as a compact disc (CD) or floppy disk, etc.), such that a device may obtain the various methods upon coupling or providing the storage means to the device.

It is to be understood that the claims are not limited to the precise configuration and components illustrated above. Various modifications, changes and variations may be made in the arrangement, operation and details of the systems, methods, and apparatus described herein without departing from the scope of the claims.

What is claimed is:

1. A method for reducing energy consumption of a base station, comprising:

receiving, at the base station, instructions from a radio network controller (RNC) to reduce energy consumption, wherein based on the instructions, the base station performs:

transmitting a first pilot channel via a first antenna using a first downlink power amplifier;

transmitting a second pilot channel via a second antenna using a second downlink power amplifier;

determining that no multiple-input and multiple-output users are in a cell corresponding to the base station; and

shutting off the second pilot channel and the second downlink power amplifier; and

transmitting only the first pilot channel via the first antenna using the first downlink power amplifier in response to shutting off the second pilot channel and the second downlink power amplifier.

2. The method of claim 1, wherein the base station is a Node B.

3. The method of claim 1, wherein the method is performed by a radio network controller via instructions sent to the base station.

4. The method of claim 1, wherein the first pilot channel and the second pilot channel are used for multiple-input and multiple-output transmissions to a user equipment.

5. A wireless device configured for reducing energy consumption, comprising:

a processor configured to receive instructions from a radio network controller (RNC) to reduce energy consumption at the wireless device, wherein based on the instructions, the processor is configured to:

transmit a first pilot channel via a first antenna using a first downlink power amplifier;

transmit a second pilot channel via a second antenna using a second downlink power amplifier;

determine that no multiple-input and multiple-output users are in a cell corresponding to the wireless device; and

shut off the second pilot channel and the second downlink power amplifier; and

17

transmit only the first pilot channel via the first antenna using the first downlink power amplifier in response to shutting off the second pilot channel and the second downlink power amplifier; and

a memory in electronic communication with processor. 5

6. The wireless device of claim 5, wherein the wireless device is a Node B.

7. The wireless device of claim 5, wherein the wireless device receives instructions from a radio network controller.

8. The wireless device of claim 5, wherein the first pilot channel and the second pilot channel are used for multiple-input and multiple-output transmissions to a user equipment. 10

9. A wireless device configured for reducing energy consumption, comprising:

means for receiving instructions from a radio network controller (RNC) to reduce energy consumption at the wireless device; 15

means for transmitting, based on the instructions, a first pilot channel via a first antenna using a first downlink power amplifier; 20

means for transmitting, based on the instructions, a second pilot channel via a second antenna using a second downlink power amplifier;

means for determining, based on the instructions, that no multiple-input and multiple-output users are in a cell corresponding to the wireless device; and 25

18

means for shutting off, based on the instructions, the second pilot channel, and the second downlink power amplifier; and

means for transmitting, based on the instructions, only the first pilot channel via the first antenna using the first downlink power amplifier in response to shutting off the second pilot channel and the second downlink power amplifier.

10. A non-transitory computer-readable medium having instructions for reducing energy consumption of a base station, the instructions comprising:

code for causing a base station to transmit a first pilot channel via a first antenna using a first downlink power amplifier;

code for causing the base station to transmit a second pilot channel via a second antenna using a second downlink power amplifier;

code for causing the base station to determine that no multiple-input and multiple-output users are in a cell corresponding to the base station; and

code for causing the base station to shut off the second pilot channel and the second downlink power amplifier; and code for transmitting only the first pilot channel via the first antenna using the first downlink power amplifier in response to shutting off the second pilot channel and the second downlink power amplifier.
